

Problem Statement: AI Chatbot using n8n

Project Title: AI-Powered Search Chatbot Automation using n8n

Background

Users often need quick answers from web sources without manually searching multiple websites. Traditional search engines return links, requiring users to open and analyze several pages. An automated chatbot can simplify this process by accepting a query, searching the web, extracting relevant information, and returning a concise response.

Problem Statement

Design and develop an AI chatbot workflow using n8n that accepts user questions, retrieves relevant information from online search services, processes the results, and generates a clear and meaningful response automatically. The system should reduce the effort required to find information while providing fast and accurate answers.

Objectives

- Accept natural language queries from users.
- Fetch search results using an external search API.
- Extract useful information from the API response.
- Format and return concise answers.
- Automate the entire process through an n8n workflow.

Workflow Overview

Trigger → User Query Input → HTTP Request (Search API) → Data Processing → Response Generation

Expected Outcome

A fully automated AI chatbot capable of answering user questions by integrating search APIs and workflow automation in n8n, improving information accessibility and reducing manual search effort.
